##
##
## Attaching package: 'lessR'
##
## The following objects are masked from 'package:dplyr':
##
##   recode, rename
```

```
library(DT)
library(e1071)
```

```
##
## Attaching package: 'e1071'
##
## The following object is masked from 'package:lessR':
##
##   kurtosis
```

Load the water pollution data into R.

```
##      Type          Density      Strength
## Length:20      Min.   :0.8700  Min.   :390.0
## Class :character 1st Qu.:0.9375  1st Qu.:482.5
## Mode  :character Median :0.9800  Median :555.0
##              Mean   :0.9740  Mean   :541.5
##              3rd Qu.:1.0200  3rd Qu.:602.5
##              Max.   :1.0400  Max.   :650.0
```

1. the **MEAN** Strength.

```
round(mean(df_strenth$Strength),2)
```

```
## [1] 541.5
```

1.1. the **MEDIAN** Strength.

```
round(median(df_strenth$Strength),2)
```

```
## [1] 555
```

2. Now calculate the **STANDARD DEVIATION** for the Strength.

```
round(sd(df_strenth$Strength),2)
```

```
## [1] 73.86
```

2.1

```
round(var(df_strenth$Strength),2)
```

```
## [1] 5455.53
```

3. What is the **inter-quartile range** for Strength column?

```
# Calculate the IQR for the specified column  
round(iqr_value <- IQR(df_strenth$Strength),2)
```

```
## [1] 120
```

```
# Print the IQR  
print(iqr_value)
```

```
## [1] 120
```

4. Using the Interquartile range technique, how many **OUTLIER** years are there in your **Strenght** column?

```

# Calculate the quartiles and IQR
q1 <- quantile(df_strenth$Strength, 0.25, na.rm = TRUE)
q3 <- quantile(df_strenth$Strength, 0.75, na.rm = TRUE)
iqr <- q3 - q1

# Define the lower and upper bounds for outliers
lower_bound <- q1 - 1.5 * iqr
upper_bound <- q3 + 1.5 * iqr

# Identify outlier years
outlier_years <- df_strenth$Strength < lower_bound | df_strenth$Strength > upper_bound

# Count the number of outlier years
num_outliers <- sum(outlier_years)

# Print the number of outlier years
print(num_outliers)

```

```
## [1] 0
```

5. Now, for the **Density** column, calculate the **skewness**, **standard error of skewness (SES)**, **kurtosis**, **standard error of kurtosis (SEK)**, and perform the **normality test with Shapiro-Wilk test**. Based on all of these parameters, determine if the Density is normally distributed.

```

# Calculate Pearson's skew
skew <- skew(df_strenth$Density)
# Print the skew rounded to 2 decimal places
print(round(skew, 2))

```

```
## [1] -0.48
```

- 5.1. Calculate the **standard error of skew (ses)** for this data so we can determine the significance of our skew.

```

# Calculate the skewness and standard error of skew
ses <- round(sqrt(6/length(df_strenth$Density)),2)
ses

```

```
## [1] 0.55
```

10. Based on the ses technique, is this **skew significant**?
No

11. Now determine the **kurtosis for the Yearly Mean Snow Depth data**.

```
kurtosis <- round(kurtosis(df_strenth$Density, type = 1) - 3, 2)
kurtosis
```

```
## [1] -3.91
```

12. Calculate the **standard error of kurtosis (sek)** for this data so we can determine the significance of our skew.

```
# Calculate standard error of kurtosis (SES)
ses_kurt <- round(sqrt(24/length(df_strenth$Density)),2)
ses_kurt
```

```
## [1] 1.1
```

13. Based on the sek technique, is this **kurtosis significant**? **No**
14. Based on your statistical summary values, do you think that your data is normally distributed? **No**
15. Is your data normally distributed? How can you tell? Be sure to report your certainty of this conclusion.

```
shapiro.test(df_strenth$Density)
```

```
##
## Shapiro-Wilk normality test
##
## data: df_strenth$Density
## W = 0.93122, p-value = 0.163
```

```
hist(df_strenth$Density, breaks = 10)
```

Histogram of df_strenth\$Density
